IMAGE PROCESSING APPARATUS, IMAGE PROCESSING METHOD AND PROGRAM, AND IMAGING APPARATUS

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an image processing apparatus and, more particularly, to an image processing apparatus for executing an image processing of image data picked up by, for example, a light field camera.

2. Description of the Related Art

An imaging apparatus using a method called "Light Field Photography" is proposed (the Official Gazette of Japanese Patent Application Laid-Open No. 2009-124213 or the Official Gazette of Japanese Patent Application Laid-Open No. 2012-129654). The imaging apparatus is constructed in such a manner that an ML array constructed by a plurality of microlenses (hereinbelow, referred to as MLs) is used and, in addition to intensity distribution of light on a light receiving surface of an imaging element, directional information of the light can be also obtained. It is also constructed in such a manner that after the image pickup, by using the obtained intensity distribution and directional information of the light, an image can be reconstructed on the basis of a set arbitrary viewpoint and a set arbitrary focus position. In the Description, such an imaging apparatus is called "light field camera". In the light field camera, in addition to information of a position where the rays of light from an object enters an imaging plane, light ray information including information of an angle of incidence is obtained. The light ray information is called light field data (hereinbelow, referred to as LF data). An image in which the focus position of the image is changed after the image pickup can be reconstructed by using the LF data.

In the light field camera, since a ray of light corresponding to one pixel of a camera in the related art is divided by the MLs and handled as a plurality of pixel data, an amount of the data increases in proportion to the number of division. For example, assuming that the division number is equal to (5 in the vertical direction×5 in the lateral direction), the data of (5×5) pixels per ML is obtained, so that the data amount is increased by 25 times. As mentioned above, there is such a problem that the data amount of the LF data is extremely larger than an amount of data of the image picked up by an ordinary camera.

Therefore, in order to compress and store an information amount of the extremely large LF data, an importance is attached to a compression encoding technique.

The invention is made in consideration of such a point and it is an aspect of the invention to provide an encoding method suitable to compress an information amount in, for example, LF data or the like and to provide an image processing apparatus or the like for encoding, for example, LF data or the like by the proposed encoding method.

SUMMARY OF THE INVENTION

To accomplish the above aspect, according to the invention, an image processing apparatus comprises: a plurality of optical systems arranged two-dimensionally; and a plurality of photoelectric conversion elements which are two-dimensionally arranged for each of the plurality of optical systems and are used to photoelectrically convert an image from each of the optical systems, wherein a plurality of image frames

2

each having a different parallax, which is formed by the plurality of photoelectric conversion elements are inter-frame prediction encoded.

Further features of the present invention will become apparent from the following description of exemplary embodiments with reference to the attached drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate exemplary embodiments, features, and aspects of the invention and, together with the description, serve to explain the principles of the invention.

FIG. 1 is a block diagram illustrating a construction of an imaging apparatus to which an image processing apparatus according to the first embodiment of the invention is applied.

FIGS. 2A and 2B are diagrams illustrating positional relations among a main lens, MLs, and an imaging element in the imaging apparatus in FIG. 1.

FIG. 3 is a diagram conceptually illustrating optical paths of rays of light from an object in the positional relations in FIGS. 2A and 2B.

FIG. 4 is a diagram illustrating a relation between LF data and image frames.

FIG. 5 is a diagram illustrating an example of reference relations among image frames in an inter-frame prediction in the parallax direction according to the first embodiment of the invention.

FIG. 6 is a diagram illustrating a direction in which a pixel of each image frame is shifted in a refocus processing in the image processing apparatus according to the first embodiment of the invention.

FIG. 7 is a diagram illustrating an example of reference relations among image frames in an inter-frame prediction in the time direction according to the second embodiment of the invention.

FIG. 8 is a diagram illustrating another example of reference relations among image frames in an inter-frame prediction in the time direction according to the second embodiment of the invention.

FIG. 9 is a flowchart regarding the operation of an image pickup processing according to each embodiment of the invention.

FIG. 10 is a flowchart regarding the operation of an encoding processing according to each embodiment of the invention.

DESCRIPTION OF THE EMBODIMENTS

Various exemplary embodiments, features, and aspects of the present invention will be described in detail below with reference to the drawings.

First Embodiment

FIG. 1 is a block diagram illustrating an example of a construction of an imaging apparatus which can pick up LF data and to which an image processing apparatus according to the first embodiment of the invention is applied.

In the diagram, a whole imaging apparatus 100 is illustrated. As component elements, the imaging apparatus 100 includes a main lens 101, a microlens (ML) 102, an imaging element 103, a data input unit 104, a data conversion unit 122, an image output unit 109, and a display panel 110. The imaging apparatus 100 further includes an image encoding/decoding unit 111, a multiplex/demultiplex unit 113, a

refocus processing unit **114**, a memory **116**, a medium I/F **117**, a recording medium **118**, a controller **119**, an operation unit **120**, and a memory bus **121**. Portions excluding the main lens **101**, ML **102**, imaging element **103**, medium I/F **117**, recording medium **118**, and operation unit **120** correspond to the image processing apparatus according to the embodiment. Each component element will be described hereinafter.

Component elements which are connected to the memory bus **121** and will be described hereinafter transmit and receive data to/from the memory **116** and execute a data processing. The memory **116** is a dynamic RAM which can be accessed at random at a high speed. The memory **116** stores image data being processed and information necessary for the processing and provides a work area to the controller. The memory bus **121** arbitrates memory access requests from the component elements and controls so that data writing and reading operations to/from the memory **116** can be performed in a time-division manner.

The main lens **101** is an imaging optical system constructed by one or a plurality of photographing lenses. The main lens **101** receives object light from a front surface (left side in the diagram) and inputs to the ML **102**. A focus function and a zoom function may be provided for the main lens **101**.

The ML **102** is arranged between the main lens **101** and the imaging plane of the imaging element **103**, separates the ray of light from the main lens **101** in accordance with an angle of incidence, and functions as a pupil division means. The imaging element **103** is an imaging sensor such as CCD, CMOS sensor, or the like. In the imaging element **103**, a plurality of pixels (photoelectric conversion elements) are arranged in a matrix form, convert the rays of light input from the ML **102** into electric signals, and output as a picked-up image to the data input unit **104**.

The data input unit **104** converts the picked-up image which is input from the imaging element **103** into digital RAW data and stores into an RAW data area in the memory **116**. The data conversion unit **122** reads out the RAW data stored in the RAW data area in the memory **116**, executes a development processing, and converts into LF data (**401** in FIG. 4). Further, a plurality of image frames (**411**, **412**, . . . , and **435** in FIG. 4) each having a different parallax are constructed from the LF data and stored into an image signal area in the memory **116**. The operations of the main lens **101**, ML **102**, imaging element **103**, data input unit **104**, and data conversion unit **122** will be described in detail hereinafter.

The image encoding/decoding unit **111** encodes and decodes the image signal. Although the operation will be described in detail hereinafter, it will be schematically described below.

At the time of image pickup, a plurality of image frames (image data to be encoded) written in the image signal area in the memory **116** are read out and encoded by the data conversion unit **122** by using a prediction between images. Stream data obtained after the encoding is stored into an image stream data area in the memory **116**. The stream data is read out from the image stream data area in the memory **116** and decoded. The decoded image frames are stored into an image signal area.

The refocus processing unit **114** reads out the image frames stored in the image signal area in the memory **116**, executes a refocus processing, generates refocus image frames, and stores into the image signal area in the memory **116**. The refocus processing will be described in detail hereinafter.

The multiplex/demultiplex unit **113** multiplexes and demultiplexes the image stream data. At the time of image pickup, a plurality of encoded image stream data are read out of the memory **116**, are multiplexed by a predetermined format, and are stored as multiplexed data into a multiplexed stream data area in the memory **116**. Upon reproduction, the multiplexed stream data is read out from the multiplexed stream data area in the memory **116**, is separated into a plurality of image stream data by a predetermined method, and is stored into the image stream data area in the memory **116**.

The medium I/F **117** is an interface for controlling the writing and reading (recording and reproduction) of data into/from the recording medium **118**. At the time of image pickup, the multiplexed stream data stored in the multiplexed stream data area in the memory **116** is read out and stored into the recording medium **118**. Upon reproduction, the multiplexed stream data is read out of the recording medium **118** and stored into the multiplexed stream data area in the memory **116**. The data is recorded into the recording medium **118** by a file system format such as FAT or the like. A generation, control, and the like of a file system are also performed by the medium I/F **117**.

The recording medium **118** is a hard disk drive or a nonvolatile semiconductor memory (for example, flash memory).

The image output unit **109** reads out a refocus image, which will be described hereinafter, from the area for the image signal in the memory **116** and outputs to the display panel **110** and an image output terminal (not shown). The display panel **110** displays the image signal, as a video image, which is input from the image output unit **109**.

The operation unit **120** indicates operation members such as shutter button, setting button, touch panel sensor arranged on the surface of the display panel **110**, and the like which are operated by the user. A result of the user's operation is transmitted as an operation instruction signal to the controller **119**.

The controller **119** controls the whole imaging apparatus and includes what is called a CPU. By executing a corresponding program in response to a user's instruction which is input through the operation unit **120**, the controller **119** controls the image pickup operation, reproducing operation, and refocus operation. The program is stored in a memory (not shown). The CPU loads and executes the program, thereby controlling each unit of the imaging apparatus.

Subsequently, the operations of the main lens **101**, ML **102**, imaging element **103**, data input unit **104**, data conversion unit **122**, and image encoding/decoding unit **111** will be described in detail.

FIGS. 2A and 2B are diagrams illustrating positional relations among the main lens **101**, MLs **102**, and imaging element **103** in the imaging apparatus illustrated in FIG. 1. The same portions as those in FIG. 1 are designated by the same reference numerals and their description is omitted here.

In the diagrams, pixels **204** construct a two-dimensional pixel array of the imaging element **103**.

As illustrated in FIG. 2A, a plurality of MLs **102** are arranged on the front surface of the imaging element **103** in a matrix form (two-dimension) (ML array). A size of ML and the number of MLs in the embodiment are not limited to those illustrated in the diagrams.

As illustrated in FIG. 2B, the pixels **204** are arranged in a matrix form (two-dimension) in such a manner that a predetermined number (nxm) of pixels correspond to one ML. The number of division of the rays of light is deter-

5

mined by the number ($n \times m$) of pixels. In the present embodiment, it is assumed that the division number of the rays of light is equal to (5×5). The imaging element **103** has a two-dimensional pixel array in which (5×5) pixels are arranged to one ML.

FIG. **3** conceptually illustrates optical paths of the rays of light from an object in the positional relations illustrated in FIGS. **2A** and **2B**. That is, FIG. **3** illustrates the optical paths at the time when light **307** emitted from one point of an object **305** enters the main lens **101** as rays of light. The entered rays of light are converged by the main lens **101** and enter an imaging plane **308** of the surface of the ML **102**. The entered light is separated in accordance with the angle of incidence of the light by the ML **102** and received by pixels **321** to **325** of the imaging element **103**. The light received by the pixels **321** to **325** is output as image pickup signals through a photoelectric conversion.

The light received by the pixel **321** is the ray of light from an optical path **311**. The light received by the pixel **322** is the ray of light from an optical path **312**. The light received by the pixel **323** is the ray of light from an optical path **313**. The light received by the pixel **324** is the ray of light from an optical path **314**. The light received by the pixel **325** is the ray of light from an optical path **315**. Although the rays of light received by the pixels **321** to **325** are the light from the same object, they are the light rays which pass through different pupil areas of the main lens plane and can be regarded as rays of light each having a different parallax.

Although an example in which the light **307** from one point of the object **305** is picked up by the pixels has been described with reference to FIG. **3**, actually, an infinite number of rays of light enter the main lens from all objects of the front surface of the main lens in such a manner that the object image is focused onto the whole MLs. Each ML separates the incident light and emits to the ($n \times m$) pixels of the imaging element **103**. Thus, a plurality of images each having a different parallax (hereinbelow, referred to as parallax images) are focused on each of the ($n \times m$) pixels corresponding to each ML in the imaging element.

The data input unit **104** converts the picked-up image which is picked up as mentioned above into the digital RAW data and stores into the RAW data area in the memory **116**. The data conversion unit **122** reads out the RAW data stored in the RAW data area in the memory **116**, executes the development processing, and converts into the LF data. Since the parallax image is picked up at each of the ($n \times m$) pixels corresponding to each ML for the LF data, the parallax image can be obtained by constructing an image by collecting the pixel data of the same position to each ML. Therefore, the data conversion unit **122** constructs a plurality ($n \times m$) of image frames each having a different parallax from the LF data as follows.

FIG. **4** is a diagram illustrating a relation between the LF data and pixel data of the image frames at the time of generating the image frames. In the diagram, the same portions as those in FIG. **1** are designated by the same reference numerals and their description is omitted here.

In FIG. **4**, positions **402** to **405** of the MLs are shown, circles shown by **1** to **25** are the LF data corresponding to one ML, and the image frames **411**, **412**, . . . , and **435** each having a different parallax are illustrated.

The image frame **411** is constructed by collecting the LF data **1** at the end of the left-hand side of the first row among the LF data **1** to **25** corresponding to each ML. Although only the LF data (only four pixels) corresponding to the four MLs are illustrated in FIG. **4**, actually, the LF data at the end

6

of the left-hand side of the first row corresponding to each of all the MLs in the LF data **401** is target data of collection.

The image frame **412** is constructed by collecting the second LF data **2** from the end of the left-hand side of the first row among the LF data **1** to **25** corresponding to each ML. Although only the LF data (only four pixels) corresponding to the four MLs are illustrated in FIG. **4** in a manner similar to the image frame **411**, actually, the second LF data from the end of the left-hand side of the first row corresponding to each of all the MLs in the LF data **401** is target data of collection.

Similarly, by collecting the LF data **3** to **25** of each ML, the corresponding image frames **413** to **435** (the image frames **413** to **434** are not shown) are constructed, and total **25** image frames **1** to **25** are constructed from the LF data obtained through the image pickup of one time.

There is a case where an enough light amount is not obtained in the pixels locating near four corners for the ML. This is because since the main lens **101** and the ML **102** are circular, a vignetting occurs. In such a case, for example, it is also possible to construct in such a manner that the image frames obtained by collecting the LF data **1**, **5**, **21**, and **25** locating at the four corners are not constructed. In this case, in the encoding processing, decoding processing, and refocus processing, which will be described later, the non-constructed image frames **1**, **5**, **21**, and **25** are not used.

The data conversion unit **122** stores the image frames **1** to **25** constructed as mentioned above into the image signal area in the memory **116**.

The image frames **1** to **25** stored in the image signal area in the memory **116** are encoded by the image encoding/decoding unit **111**.

Subsequently, the encoding operation in the image encoding/decoding unit **111** will be described in detail.

In the present embodiment, it is assumed that the image encoding/decoding unit **111** uses a motion compensation prediction encoding method represented by MPEG2, H.264, or the like. As an encoding method, there are an intra-frame encoding in which the encoding is completed in the same image frame and an inter-frame prediction encoding in which the prediction is performed among a plurality of image frames.

In the motion compensation prediction encoding method, the image is separated into predetermined encoding blocks (macro blocks of 16×16 pixels), a motion compensation prediction and an orthogonal transform are performed, further, conversion coefficients are quantization-processed, and an entropy encoding is performed, thereby compression-encoding the image.

Since each of the image frames **1** to **25** (collectively referred to as an image frame group) is a parallax image and the image frames mutually have a high correlation, by executing the inter-frame prediction encoding, a high encoding efficiency can be expected.

In the present embodiment, the intra-frame encoding is performed to partial image frames in the image frame group and the inter-frame prediction encoding is performed to the other image frames. Generally, the inter-frame prediction indicates the prediction between the frames in the time direction in the motion image. However, in the present embodiment, the inter-frame prediction indicates the prediction between the image frames (**411** to **435**) each having a different parallax obtained from the LF data at the same time.

An example of the inter-frame predicting direction in the image frame group is illustrated in FIG. **5**. In this figure, **F1** to **F25** denote image frames **1** to **25** respectively. An arrow

shown between the image frames indicates the direction of the inter-frame prediction. A reference image is determined on the basis of the parallax direction.

In the example illustrated in FIG. 5, the intra-frame encoding is performed to an image frame F13 locating in the center portion of the parallax among image frames F1 to F25.

The inter-frame prediction encoding using F13 as a reference image is performed to F7, F8, F9, F12, F14, F17, F18, and F19 adjacent to F13.

The inter-frame prediction encoding using the image frame F8 as a reference image is performed to F3 adjacent to F8.

The inter-frame prediction encoding using the image frame F12 as a reference image is performed to F11 adjacent to F12.

The inter-frame prediction encoding using the image frame F14 as a reference image is performed to F15 adjacent to F14.

The inter-frame prediction encoding using the image frame F18 as a reference image is performed to F23 adjacent to F18.

The inter-frame prediction encoding using the image frame F7 as a reference image is performed to F1, F2, and F6 adjacent to F7.

The inter-frame prediction encoding using the image frame F9 as a reference image is performed to F4, F5, and F10 adjacent to F9.

The inter-frame prediction encoding using the image frame F17 as a reference image is performed to F16, F21, and F22 adjacent to F17.

Further, the inter-frame prediction encoding using the image frame F19 as a reference image is performed to F20, F24, and F25 adjacent to F19.

The inter-frame predicting direction based on the parallax direction is not limited to that shown in the diagram but may be another direction. A bidirectional prediction from a plurality of reference images may be performed as for the inter-frame prediction. Further, the image frames to be intra-frame encoded are not limited to one image frame but the apparatus may be set so as to perform the intra-frame encoding to a plurality of image frames at predetermined positions. In such a case, the inter-frame prediction of different series may be performed to the image frames in predetermined directions from each image frame to be intra-frame encoded.

Subsequently, the operations of the intra-frame encoding and the inter-frame prediction encoding in the image encoding/decoding unit 111 will be described.

In the present embodiment, the image frames 1 to 25 are encoded by the method of either the intra-frame encoding or the inter-frame prediction encoding. As encoding order of the image frames, the image frames to be intra-frame encoded are encoded first and, after that, the image frames to be inter-frame encoded are encoded. For example, in the present embodiment, the encoding is performed in the following order.

F13
 →F8→F3
 →F12→F11
 →F14→F15
 →F18→F23
 →F7→F6→F1→F2
 →F9→F4→F5→F10
 →F17→F16→F21→F22
 →F19→F20→F24→F25

In the intra-frame encoding, the image frame (for example, F13) to be encoded is read out from the image signal area in the memory 116 and an orthogonal transform, a quantization of the conversion coefficients, and an entropy encoding are sequentially performed on an encoding block (for example, 16×16 pixels) unit basis, thereby obtaining stream data. Information such as quantization parameters which is necessary to decode is contained in the stream data. The stream data is stored in the image stream data area in the memory 116. At the same time, an inverse quantization of the quantized conversion coefficients and an inverse orthogonal transform are performed, thereby obtaining a local decoding image. The local decoding image is stored in the reference frame area in the memory 116.

In the inter-frame prediction encoding, the image frame (for example, F7) to be encoded is read out from the image signal area in the memory 116 and an image (local decoding image) obtained by encoding and decoding the image frame (for example, F13) serving as a reference destination is read out. A motion search is performed every encoding block to detect a motion vector, and a prediction image is generated. Subsequently, a difference (error) between the prediction image and the image data to be encoded is obtained. To such a difference, the orthogonal transform, the quantization of the conversion coefficients, and the entropy encoding are sequentially performed on an encoding block unit basis, thereby obtaining stream data. The stream data includes information such as quantization parameters which is necessary to decode, reference image frame number, motion vector, and the like. The stream data is stored in the image stream data area in the memory 116. At the same time, the quantized conversion coefficients are inversely quantized, are inversely orthogonal-transformed, and are added to the prediction image, thereby obtaining the local decoding image. The local decoding image is stored in the reference frame area in the memory 116.

A plurality of stream data in which the image frames 1 to 25 are encoded as mentioned above are multiplexed by the multiplex/demultiplex unit 113 in encoding order. As header information, information such as the number of image streams, parallax positional relation, and the like is also simultaneously multiplexed to the multiplexed stream. The multiplexed stream data is temporarily stored into the multiplexed stream area in the memory 116 and, thereafter, is read out by the medium I/F 117, and is recorded into the recording medium 118.

Subsequently, the operation of the image encoding/decoding unit 111 upon reproduction will be described in detail.

The multiplexed stream recorded in the recording medium 118 is read out by the medium I/F 117 and is stored into the multiplexed stream area in the memory 116. The multiplex/demultiplex unit 113 reads out the multiplexed stream from the multiplexed stream area in the memory 116 and stores the image streams into the image stream area in the memory 116 in accordance with the information such as the number of image streams, parallax positional relation, and the like included in the header information of the multiplexed stream.

The image encoding/decoding unit 111 reads out the image streams from the image stream area in the memory 116 and entropy-decodes them to obtain the quantization coefficients, and thereafter, performs the inverse quantization and inverse orthogonal transform to obtain the decoded image frames. In the case of the intra-frame encoding, the decoded image frames are stored as they are into the image signal area in the memory 116. In the case of the inter-frame

prediction encoding, the image frame of the reference destination is read out, the motion compensation processing is executed, and the obtained image frame is stored in the image signal area in the memory **116**.

By performing the decoding as mentioned above, the decoded images of the image frames 1 to 25 are stored in the image signal area in the memory **116**.

Subsequently, the generating operation of a refocus image in the image processing apparatus of the embodiment will be described.

In the image processing apparatus of the present embodiment, the refocus image can be generated in both of the case of image pickup and the case of reproduction. In any case, the refocus image is generated from the image frames 1 to 25 stored in the image signal area in the memory **116** by the refocus processing unit **114**. At the time of image pickup, as for the image frames 1 to 25 stored in the image signal area in the memory **116**, the refocus image is generated from the image frames which are constructed by the data conversion unit **122** and are stored in the memory **116**. At the time of reproduction, the refocus image is generated from the image frames which are decoded by the image encoding/decoding unit **111** and are stored in the memory **116**.

The refocus image is generated by one of the following two methods.

According to the first refocus method, a position in a depth of focus (position of a focal point) is designated and the refocus is performed. Each of the pixel data of the image frames 1 to 25 is shifted in the parallax direction to be integrated, thereby generating the refocus image. The parallax direction is a direction which is determined by the positional relations of the image frames to the center image frame. As illustrated in FIG. 6, for example, in the case of the image frame F1, the parallax direction is a direction shown by **601**, in the case of the image frame F2, it is a direction **602**, and in the case of the image frame F3, it is a direction **603**. The refocus position can be changed in dependence on a shift amount of the pixel data.

According to the second refocus method, the user designates an area (object) of the image to be focused to generate the refocus image. Each of the pixel data of the image frames 1 to 25 is shifted on the basis of the motion vector information detected in the encoding of the image frames and integrated, thereby generating the refocus image. When the user designates an area of the image to be focused through the operation unit **120**, the refocus processing unit **114** obtains motion vector information of the encoding blocks around such an area from the image streams of the image frames 1 to 25. A motion vector from the center image frame in each image frame is calculated, respectively. By shifting the pixel data of each image frame in accordance with the motion vector and integrating, the refocus image is generated.

The refocused images obtained as mentioned above are stored into the image signal area in the memory **116**. The stored refocus images are output to the display panel **110** and an image output terminal (not shown) by the image output unit **109** mentioned above. It is also possible to construct in such a manner that the controller **119** controls each unit of the imaging apparatus **100**, encodes the refocus image, and controls the medium I/F **117** to record the encoded refocus image to the recording medium **118**.

As described above, according to the present embodiment, since a plurality of image frames as parallax images are constructed from the LF data and the prediction encoding

in the parallax direction is performed, a compression encoding of a high compression ratio can be realized and the data amount can be reduced.

The operation of each unit of the image processing apparatus of the present embodiment mentioned above may be executed by a method whereby a CPU of the controller **119** loads a program from a memory (not shown) and executes. In such a case, as an electronic processing, the image processing apparatus of the embodiment can be provided as a function which is executed by a CPU of an information processing apparatus such as a PC or the like.

FIGS. 9 and 10 illustrate flowcharts for the image processing operation at the time when the CPU of the controller **119** functions as each unit of the image processing apparatus of the present embodiment. The flowcharts of FIGS. 9 and 10 are diagrams illustrating a processing procedure which is executed by the controller **119** and are realized by a method whereby the program stored in the memory (ROM) held in the controller **119** is developed into the memory (RAM) and the CPU executes it.

First, the operation at the time of image pickup will be described with reference to the flowchart of FIG. 9. The main lens **101**, ML **102**, imaging element **103**, and data input unit **104** among the foregoing component elements operate in a manner similar to that mentioned above. The picked-up image signal is stored as unprocessed RAW data into the RAW data area in the memory **116**. The subsequent image processing is executed by the CPU of the controller **119**.

FIG. 9 is the flowchart showing the processing procedure at the time of image pickup which is executed by the CPU of the controller **119**. In step S901, the image pickup operation is started. Steps S902 to S907 are executed as an image processing of the image data obtained by the image pickup operation of one time.

In step S902, a data conversion processing is executed. This step is a processing corresponding to the foregoing data conversion unit **122**. The RAW data is read out from the RAW data area in the memory **116**, a development processing is executed, and the RAW data is converted into LF data. A plurality of (n×m) image frames (image frame group) each having a different parallax are constructed from the LF data in a manner similar to that mentioned above and are stored into the image signal area in the memory **116**.

Subsequently, in step S903, the constructed image frame group is encoded. This step is a processing corresponding to the foregoing encoding processing in the image encoding/decoding unit **111**. The image frame group is encoded by a motion compensation prediction method. The encoded stream data is stored into the stream data area in the memory **116**. A flow for the encoding processing will be described in detail hereinafter.

Subsequently, in step S904, a multiplex processing of the plurality of encoded stream data is executed. This step is a processing corresponding to the multiplex processing of the foregoing multiplex/demultiplex unit **113**. The plurality of stream data are read out from the stream data area in the memory **116** and multiplexed. As header information, information such as the number of image streams, parallax positional relation, and the like is also simultaneously multiplexed to the multiplexed stream. The obtained multiplexed stream data is stored into the multiplexed stream data area in the memory **116**.

Subsequently, in step S905, the multiplexed stream data is recorded to the recording medium. The multiplexed stream data stored in the multiplexed stream data area in the memory **116** is read out and recorded to the recording medium **118** through the medium I/F **117**.

11

Subsequently, in step S906, the refocus processing is executed. This step corresponds to the foregoing refocus processing unit 114. The refocus image is generated from the image frame group and stored into the image signal area in the memory 116.

Subsequently, in step S907, the generated refocus image is output as a monitor image. Control is made in such a manner that the refocus image stored in the image signal area in the memory 116 is output to the display panel 110 and the image output terminal (not shown) through the image output unit 109.

As mentioned above, the processing procedure of the CPU of the controller 119 in the image pickup operation in the first embodiment is executed.

Subsequently, a detailed procedure for the encoding processing in step S903 will be described with reference to the flowchart of FIG. 10.

FIG. 10 is the flowchart showing the detailed procedure for the encoding processing (step S903) of the CPU of the controller 119 in the image pickup operation in the first embodiment.

In step S1001, the encoding processing is started. In step S1002, parameters regarding the encoding of the image frame to be encoded are determined. As parameters regarding the encoding, there are a frame number of the image frame to be encoded, a prediction method (either the intra-frame or the inter-frame), a frame number of the reference image frame, and the like.

The following processings of steps S1003 to S1009 are repetitively executed on the encoding block unit basis until the processing of one image frame is completed.

Step S1003 is executed only at the time of the inter-frame encoding and a prediction image at the time of the inter-frame encoding is generated. The image frame to be encoded is read out from the image signal area in the memory 116 and the local decoding image of the image frame serving as a reference destination is also read out. A motion search is performed to detect a motion vector, and a prediction image is generated.

Subsequently, in step S1004, an orthogonal transform is performed. At the time of the intra-frame encoding, the image frame to be encoded is read out from the image signal area in the memory 116 and is orthogonal-transformed. At the time of the inter-frame encoding, the orthogonal transform is performed to a difference between the prediction image and the image data to be encoded.

Subsequently, in step S1005, a quantization is performed to the orthogonal-transformed conversion coefficients.

Subsequently, in step S1006, an inverse quantization is performed to the quantized conversion coefficients.

Subsequently, in step S1007, an inverse orthogonal transform is performed to the inverse-quantized conversion coefficients.

Subsequently, in step S1008, a local decoding image is generated. At the time of the intra-frame encoding, the data obtained by the inverse orthogonal transform is set to local decoding image data. At the time of the inter-frame encoding, the data obtained by the inverse orthogonal transform and the prediction image generated in step S1003 are added, thereby forming a local decoding image. The obtained local decoding image is stored into the reference frame area in the memory 116.

Subsequently, in step S1009, an entropy encoding is performed to the quantized conversion coefficients obtained in step S1005 and the motion vector obtained in step S923, thereby obtaining stream data.

12

In step S1010, whether or not all of the processings of the encoding block unit in steps S1003 to S1009 mentioned above are completed with respect to one image frame is discriminated. If they are not completed yet, the processing routine is returned to S1003. If they are completed, S1011 follows.

In step S1011, whether or not the encoding processing to all of the image frame groups is completed is discriminated. If it is not completed yet, the processing routine is returned to S1002. If it is completed, S1003 follows and the encoding processing is finished.

Second Embodiment

Subsequently, the second embodiment of the invention will be described. Although the first embodiment is described with respect to the example of the prediction encoding in the parallax direction of the LF data obtained by the image pickup operation of one time of the imaging apparatus, the second embodiment will be described with respect to a construction in which a plurality of continuous LF data obtained by the image pickup of a moving image are encoded. An example of the construction of the imaging apparatus in the second embodiment is similar to that in the first embodiment and a description of component elements is omitted here.

The second embodiment differs from the first embodiment with respect to a point that the prediction encoding in the parallax direction is performed by the image encoding/decoding unit 111 in each image frame group obtained from the same LF data and, at the same time, the inter-frame prediction encoding in the time direction is also performed between the image frame groups which are temporally neighboring. Other component elements are similar to those in the first embodiment and a description of them is omitted here. Flowcharts for the image processing operation at the time when the CPU of the controller 119 functions as each unit of the image processing apparatus of the embodiment are also similar to those in FIGS. 9 and 10. As will be described hereinafter, the encoding processing has contents according to such a result that the number of predicting directions in the prediction encoding is increased as compared with that in the first embodiment.

At the time of image pickup, the image encoding/decoding unit 111 operates so as to execute the inter-frame prediction encoding in the time direction in addition to the inter-frame prediction encoding in the parallax direction shown in the first embodiment.

One example of the predicting directions in the inter-frame prediction in the parallax direction and the time direction is illustrated in FIG. 7. FIG. 7 illustrates each image frame group of data of moving images picked up at time t0 to t3. An image frame group 701 is constructed by the image frames 1 to 25 at time t0. This is true of image frame groups 702 to 704 and they are constructed by the image frames 1 to 25 at time t1, t2, and t3, respectively.

In the image frame group 701, the intra-frame encoding is performed to the image frame 13 locating at the center and the inter-frame prediction encoding in the parallax direction is performed to the other image frames.

In the image frame group 702, the inter-frame prediction encoding is performed in the time direction to the image frame 13 locating at the center by the image frames at the same position of t0 in place of the intra-frame encoding and the inter-frame prediction encoding in the parallax direction is performed to the other image frames.

13

The encoding processings are also executed to the image frame groups 703 and 704 in a manner similar to the image frame group 702.

The inter-frame predicting directions of the parallax direction and the time direction in the embodiment are not limited to those illustrated in FIG. 7. As illustrated in FIG. 8, the inter-frame prediction in the time direction may be applied to all of the image frames after t1. A bidirectional prediction in which the inter-frame prediction in the parallax direction and the inter-frame prediction in the time direction are combined may be performed from a plurality of reference images. It is desirable to construct the apparatus in such a manner that the inter-frame prediction in the time direction shown in FIG. 7 or FIG. 8 is reset after it is continued the specific number of times, and the encoding is performed again from the intra-frame encoding. By this method, an error propagation different from the actual one can be eliminated on the way of the processing. According to the foregoing embodiment, even in the encoding of the moving image in which each frame contains a plurality of parallax images, a code amount of the encoded data can be reduced by the prediction encoding to the parallax image.

Other Embodiments

Embodiments of the present invention can also be realized by a computer of a system or apparatus that reads out and executes computer-executable instructions recorded on a storage medium (e.g., non-transitory computer-readable storage medium) to perform the functions of one or more of the above-described embodiment(s) of the present invention, and by a method performed by the computer of the system or apparatus by, for example, reading out and executing the computer-executable instructions from the storage medium to perform the functions of one or more of the above-described embodiment(s). The computer may comprise one or more of a central processing unit (CPU), micro processing unit (MPU), or other circuitry, and may include a network of separate computers or separate computer processors. The computer-executable instructions may be provided to the computer, for example, from a network or the storage medium. The storage medium may include, for example, one or more of a hard disk, a random-access memory (RAM), a read only memory (ROM), a storage of distributed computing systems, an optical disk (such as a compact disc (CD), digital versatile disc (DVD), or Blu-ray Disc (BD)TM), a flash memory device, a memory card, and the like.

While the present invention has been described with reference to exemplary embodiments, it is to be understood that the invention is not limited to the disclosed exemplary embodiments. The scope of the following claims is to be accorded the broadest interpretation so as to encompass all such modifications and equivalent structures and functions.

This application claims the benefit of Japanese Patent Application No. 2013-132598, filed Jun. 25, 2013, which is hereby incorporated by reference herein in its entirety.

What is claimed is:

1. An image processing apparatus comprising:
 - a plurality of optical systems arranged two-dimensionally;
 - a plurality of photoelectric conversion elements which are two-dimensionally arranged for each of the plurality of optical systems and are used to photoelectrically convert an image from each of the optical systems; and
 - at least one processor that functions as:
 - an encoding unit configured to inter-frame prediction encode a plurality of image frames each having a

14

different parallax, which are formed by the plurality of photoelectric conversion elements; and

- a multiplex/demultiplex unit configured to generate stream data by multiplexing encoded data generated by the encoding unit and demultiplex the stream data to encoded data.

2. The image processing apparatus according to claim 1, wherein the encoding unit encodes a predetermined image frame among the plurality of image frames by an intra-frame encoding and encodes the other image frames by an inter-frame prediction encoding, and in the inter-frame prediction encoding, a reference image is determined in accordance with a parallax direction and a motion vector is detected.

3. The image processing apparatus according to claim 1, further comprising a refocus image generation unit configured to generate a refocus image from the plurality of image frames generated by the plurality of photoelectric conversion elements on the basis of an instruction of a user, wherein the at least one processor functions as the refocus image generation unit.

4. The image processing apparatus according to claim 3, wherein the refocus image generation unit generates the refocus image by shifting a pixel of each image frame in a direction of the parallax and integrating the shifted pixel.

5. The image processing apparatus according to claim 4, further comprising a decoding unit configured to decode encoded data generated by the encoding unit and generate a plurality of decoded image frames,

wherein the refocus image generation unit generates the refocus image from the plurality of decoded image frames generated by the decoding unit, wherein the at least one processor functions as the decoding unit.

6. The image processing apparatus according to claim 5, wherein the refocus image generation unit generates the refocus image by shifting a pixel of each decoded image frame on the basis of information of a motion vector detected in the prediction in the parallax direction by the encoding unit and integrating the shifted pixel.

7. The image processing apparatus according to claim 3, wherein the encoding unit encodes the refocus image generated by the refocus image generation unit.

8. The image processing apparatus according to claim 1, wherein the plurality of image frames are formed by combining a signal from at least one of the plurality of photoelectric conversion elements corresponding to one of the plurality of optical systems and a signal from at least one of the plurality of photoelectric conversion elements corresponding to the other optical systems.

9. The image processing apparatus according to claim 8, wherein the plurality of optical systems are a plurality of microlenses arranged two-dimensionally on an imaging plane of the imaging element, a predetermined number of the photoelectric conversion elements correspond to each microlens, and the plurality of photoelectric conversion elements generate one of the image frames from image data of the photoelectric conversion elements locating at a same position for the microlens among the predetermined number of the photoelectric conversion elements corresponding to each microlens.

10. The image processing imaging apparatus according to claim 1, further comprising a recording unit configured to record the stream data generated by the multiplex/demultiplex unit in a recording medium, wherein the at least one processor functions as the recording unit.

15

11. The image processing apparatus according to claim 10, further comprising a reproducing unit configured to reproduce the stream data recorded in the recording medium, and

wherein the multiplex/demultiplex unit demultiplexes the stream data reproduced from the recording medium to encoded data, wherein the at least one processor functions as the reproducing unit.

12. The image processing apparatus according to claim 11, further comprising an operation unit configured to receive an operation of a user,

wherein the control unit controls the image processing apparatus on the basis of the user's operation received by the operation unit, wherein the at least one processor functions as the operation unit.

13. The image processing apparatus according to claim 12, wherein the operation unit receives an operation for designating a focus position where a refocus image is generated or a position of an object, as an instruction of the user.

14. An image processing method using an image processing apparatus having a plurality of optical systems arranged two-dimensionally and a plurality of photoelectric conversion elements which are two-dimensionally arranged for each of the plurality of optical systems and are used to photoelectrically convert an image from each of the optical systems, comprising:

16

inter-frame prediction encoding a plurality of image frames each having a different parallax, which are formed by the plurality of photoelectric conversion elements;

generating stream data by multiplexing encoded data generated in the inter-frame prediction encoding; and demultiplexing the stream data to encoded data.

15. A non-transitory computer-readable storage medium storing a program for causing a computer to control an image processing apparatus having a plurality of optical systems arranged two-dimensionally and a plurality of photoelectric conversion elements which are two-dimensionally arranged for each of the plurality of optical systems and are used to photoelectrically convert an image from each of the optical systems,

wherein the program causes the computer to function as an encoding unit configured to inter-frame prediction encode a plurality of image frames each having a different parallax, which are formed by the plurality of photoelectric conversion elements; and a multiplex/demultiplex unit configured to generate stream data by multiplexing encoded data generated by the encoding unit and demultiplexing the stream data to encoded data.
